# On Some Properties of Middle Cube Graphs and Their Spectra 

Pandu, Rupa Lakshmi,<br>Assistant Professor,Assistant Professor, Department of Humanities and Science, Samskruti College of Engineering and Techology, Ghatkesar

#### Abstract

: In this research paper we begin with study of family of $n$ dimensional hyper cube graphs and establish some properties related to their distance, spectra, and multiplicities and associated Eigen vectors and extend to bipartite double graphs [11].In a more involved way since no complete characterization was available with experiential results in several inter connection networks on this spectra our work will add an element to existing theory.

Keywords: Middle cube graphs, distance-regular graph, antipodal graph, bipartite double graph, extended bipartite double graph, Eigen values, Spectrum, Adjacency Matrix. 3

## Introduction:

An $n$ dimensional hyper cube $Q_{n}[24]$ also called n-cube is an $n$ dimensional analogue of Square and a Cube. It is closed compact convex figure whose 1-skelton consists of groups of opposite parallel line segments aligned in each of spaces dimensions, perpendicular to each other and of same length.
1.1) A point is a hypercube of dimension zero. If one moves this point one unit length, it will sweep out a line segment, which is the measure polytypic of dimension one. If one moves this line segment its length in a perpendicular direction from itself; it sweeps out a two-dimensional square. If one moves the square one unit length in the direction perpendicular to the plane it lies on, it will generate a three-dimensional cube. This can be generalized to any number of dimensions. For example, if one moves the cube one unit length into the fourth dimension, it generates a 4-dimensional measure polytopes or tesseract.
The family of hypercube is one of the few regular polytopes that are represented in any number of dimensions. The dual polytopes of a hypercube is called a cross-polytypic.
A hypercube of dimension $n$ has $2 n$ "sides" (a 1-dimensional line has 2 end points; a 2-dimensional square has 4 sides or edges; a 3-dimensional cube has 6 faces; a 4 -dimensional Thus 8 cells). The number of vertices (points) of a hypercube is $2^{n}$ (a cube has $2^{3}$ vertices, for instance).
The number of $m$-dimensional hyper cubes on the boundary of an $n$-cube is

$$
2^{n-m}\binom{n}{m}
$$

For example, the boundary of a 4-cube contains 8 cubes, 24 squares, 32 lines and 16 vertices.

A projection of hypercube into two-dimensional image

A unit hyper cube is a hyper cube whose side has length 1 unit whose corners are

$$
V_{2^{n+1}} \leftarrow\left(\begin{array}{ll}
V_{2^{n}} & I_{2^{n}} \\
I_{2^{n}} & V_{2^{n}}
\end{array}\right)
$$

$2^{n}$ Points in $R^{n}$ with each coordinate equal to 0 or 1 termed as measure polytypic.
The correct number of edges of cube of dimension $n$ is $n \times 2^{n-1}$ for example 7 -cube has $7 \times 2^{6}=448$ edges.

## 1.2) Dimension of the cube

|  | 1 | 2 | 3 | 4 | 5 | 6 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| No. of <br> vertices | 2 | 4 | 8 | 16 | 32 | 64 |
| No. edges | 1 | 4 | 12 | 32 | 80 | 192 |

Here we define adjacency matrix of $n$ cube described in a constructive way.

$$
V_{2^{n+1}} \leftarrow\left(\begin{array}{ll}
V_{2^{n}} & I_{2^{n}} \\
I_{2^{n}} & V_{2^{n}}
\end{array}\right)
$$

Since $n Q_{n}$ is n regular bipartite graph of $2^{n}$ vertices characteristic vector of subsets of $[\mathrm{n}]=\{1,2,3, \ldots \mathrm{n}\}$ vertices of layer $L_{k}$ corresponds to subsets of cardinality k .

If n is odd $\mathrm{n}=2 \mathrm{k}-1$, the middle two layers $L_{k}, L_{k-1}$ of $Q_{n}$ with $n c_{k}, n c_{k-1}$ vertices forms middle cube graph $\mathrm{M} Q_{k}$ by induction.

As $\mathrm{M} Q_{k}$ is bipartite double graph which is a sub graph of n -cube $Q_{n}$ induced by vertices whose binary representations have either $\mathrm{k}-1$ or k no. of 1 's is of k -regular as shown in figures below

The middle cube graph $\mathrm{MQ}_{2}$ is a sub graph of $\mathrm{Q}_{3}$ or is the bipartite double graph of $Q_{2}=\mathrm{K}_{3}$.

We start with spectral properties of bipartite double graphs [17][18] and extend for study of Eigen values of $\mathrm{M} Q_{k}$.
1.3) Bipartite double graph: Let $\mathrm{H}=(\mathrm{V}, \mathrm{E})$ be a graph of order n , with vertex set $\mathrm{V}=\{1,2 \ldots \mathrm{n}\}$. Its bipartite double graph $1+\lambda,-1-\lambda \hat{H} \quad \bar{H}=(\bar{V}, \bar{E})$ is the graph with the duplicated vertex set
$\bar{V}=\left\{1,2 \ldots \mathrm{n} .1^{\prime}, 2^{\prime}, \ldots \mathrm{n}^{\prime}\right\}$ and adjacencies induced from the adjacencies in H as follows:

$$
i: j \Rightarrow\left\{\begin{array}{c}
E \\
i: j^{\prime} \\
j: i^{\prime}
\end{array}\right.
$$

Thus, the edge set of $\bar{H}$ is $\bar{E}=\left\{\mathrm{ij}^{\prime} \mid \mathrm{ij} \in \mathrm{E}\right\}$. From the definition, it follows that $\bar{H}$ is a bipartite graph [24.21] with stable subsets $V_{1}=\{1,2 \ldots \mathrm{n}\}$, and $V_{2}=\left\{1^{\prime}, 2^{\prime}, \ldots \mathrm{n}^{\prime}\right\}$. For example, if H is a bipartite graph, then its bipartite double graphs $\bar{H}$ consists of two non-connected copies of H .

Path p-4 and its bipartite Double Graph

## Graph $H$ has diameter 2 and $\bar{H}$ has diameter 3

If H is a $\delta$-regular graph, then $\bar{H}$ also, if the degree sequence of the original graph H is $\delta=\left(\delta_{1}, \delta_{2}, \delta_{3} \ldots \delta_{n}\right)$, the degree sequence for its bipartite double graph is $\bar{\delta}=\left(\delta_{1}, \delta_{2}, \delta_{3} \ldots \delta_{n}, \delta_{1}, \delta_{2}, \delta_{3} \ldots . \delta_{n}\right)$
The distance between vertices in the bipartite double graph H can be given in terms of even and odd distances in H .

$$
\begin{aligned}
& \operatorname{dist}_{\bar{H}}(\mathrm{i}, \mathrm{j})=\operatorname{dist}_{H}^{+}(\mathrm{i}, \mathrm{j}) \\
& \operatorname{dist}_{\bar{H}}\left(\mathrm{i}, \mathrm{j}^{\prime}\right)=\operatorname{dist}_{H}^{-}(\mathrm{i}, \mathrm{j})
\end{aligned}
$$

Involutive auto Orphism without fixed edges, which interchanges vertices $i$ and $i$, the map from
$\bar{H}$ Onto H defined $i^{\prime} \rightarrow i, i \rightarrow i$ is a 2 -fold covering.
If $\hat{H}$ is extended bipartite double graph by adding edges (i,i') for each $i \in V \bar{H} \equiv \hat{H}$.

## 1.4) Notations:

The order of the graph $G$ is $n=\{V\}$ and its size is $m=\{E\}$. We label the vertices with the integers $1,2, \ldots, n$. If i is (E)
adjacent to j , that $\mathrm{is}, \mathrm{ij} \in \mathrm{E}$, we write $\mathrm{i}: \mathrm{j}$ or $\mathrm{i}: ~ \mathrm{j}$. The distance between two vertices is denoted by dist $(\mathrm{i}, \mathrm{j})$. We also use the concepts of even distance and odd distance between vertices, denoted by dist+ and dist -, respectively. They are defined as the length of a shortest even (respectively, odd) walk between the corresponding vertices. The set of vertices which are L-apart from vertex i , with respect to the usual distance, is $\Gamma_{l}(i)=\{j: \operatorname{dist}(\mathrm{i}, \mathrm{j})=l$, so that the degree of vertex is simply $\Gamma_{l}(i)$. The eccentricity of a vertex is ecc $(\mathrm{i})=\max _{1 \leq X_{1 \leq j \leq n}} \operatorname{dist}(\mathrm{i}, \mathrm{j}) \max 1 \mathrm{j}_{\_} \mathrm{n}$ distt $(\mathrm{i} ; \mathrm{j})$ and the diameter of the graph is $\mathrm{D}=\mathrm{D}(\mathrm{G}) \max _{1 \leq X_{1 \leq \leq \leq n}} \operatorname{dist}(\mathrm{i}, \mathrm{j})$ graph $\mathrm{G}^{\prime}$ has the same vertex set as G and two vertices are adjacent in $\mathrm{G}^{\prime}$ if and only if they are at distance 1 in G. An antipodal graph G is a connected graph of diameter D for which GD is a disjoint union of cliques. The folded graph of G is the graph G whose vertices are the maximal cliques.
Let $\mathrm{G}=(\mathrm{V} ; \mathrm{E})$ be a graph with adjacency matrix A and $\lambda$-eigenvector v . Then, the charge of vertex $\mathrm{i} \in \mathrm{V}$ is the entry vi of v , and the equation $A v=\lambda v . \Rightarrow$ Eigen values of the bipartite double graph $[11,16] \bar{G}$ and the extended bipartite double graph $\hat{G}$ as functions of the Eigen values of a non-bipartite graph G.
2) Theorem: Let F be a field and let R be a commutative sub ring of $\mathrm{F}^{\mathrm{n} * n}$, the set of all $\mathrm{n} * \mathrm{n}$ Matrices over F . Let $\mathrm{M} \in R^{m^{*} \mathrm{~m}}$, then

$$
\begin{gathered}
\operatorname{det}_{F}(\mathrm{M})=\operatorname{det}_{F}\left(\operatorname{det}_{R}(\mathrm{M})\right) \\
\therefore \operatorname{det}_{F}(\mathrm{M})=\operatorname{det}_{F}(\mathrm{AD}-\mathrm{BC}) .
\end{gathered}
$$

for a bipartite double graph characteristic polynomial. [13]

We prove the following theorems showing geometric multiplicities of Eigen value $\lambda$ of $\mathrm{H} \Rightarrow$ geometric multiplicities of Eigen values $\lambda$ and $-\lambda$ of $\bar{H}$
$1+\lambda,-1-\lambda$ of $\hat{H}$
2.1) Theorem: Let $H$ be a graph on $n$ vertices, with the adjacency matrix $A$ and characteristic

$$
\begin{aligned}
& \bar{u}=u_{i}^{+} v_{i}(1+\lambda): \\
& \left(u^{+}\right)_{i^{\prime}}=\sum_{\substack{E \\
j: i^{\prime}}} u^{+}=\sum_{\substack{E \\
j: i}} v_{j}=\lambda v_{i}=\lambda u_{i}^{+}
\end{aligned}
$$

Polynomial $\varnothing_{H}(\mathrm{x})$. Then, the characteristic polynomials of $\bar{H}$ and $\hat{H}$ are, respectively,

$$
\begin{aligned}
& \varnothing_{:}(\mathrm{x})=(-1)^{n} \varnothing_{H}(\mathrm{x}) \varnothing_{H}(-\mathrm{x}), \\
& \varnothing_{\hat{H}}(\mathrm{x})=(-1)^{n} \varnothing_{H}(\mathrm{x}-1) \varnothing_{H}(-\mathrm{x}-1) .
\end{aligned}
$$

Adjacency matrices are, respectively,

$$
A=\left(\begin{array}{ll}
0 & A \\
A & 0
\end{array}\right) \text { and } \hat{A}=\left(\begin{array}{cc}
\mathrm{O} & \mathrm{~A}+\mathrm{I} \\
\mathrm{~A}+\mathrm{I} & \mathrm{O}
\end{array}\right)
$$

By above corollary

$$
\begin{aligned}
\varnothing_{\dot{H}}(\mathrm{x}) & =\operatorname{det}\left(\mathrm{xI}_{2 \mathrm{n}}-A\right)=\operatorname{det}\left(\begin{array}{cc}
\mathrm{xI}_{n} & -\mathrm{A} \\
-\mathrm{A} & \mathrm{xI}_{n}
\end{array}\right)=\operatorname{det}\left(\mathrm{x}^{2} \mathrm{I}_{n}-\mathrm{A}^{2}\right) \\
& =\operatorname{det}\left(\mathrm{xI}_{n}-\mathrm{A}\right) \operatorname{det}\left(\mathrm{xI}_{n}+\mathrm{A}\right)=(. .1)^{\mathrm{n}} \varnothing_{H}(\mathrm{x}) \varnothing_{H}(-\mathrm{x}) ;
\end{aligned}
$$

Whereas, the characteristic polynomial of $\hat{H}$ is

$$
\begin{aligned}
\varnothing_{\dot{H}}(\mathrm{x}) & =\operatorname{det}\left(\mathrm{xI}_{2 \mathrm{n}}-\hat{A}\right)=\operatorname{det}\left(\begin{array}{cc}
\mathrm{xI}_{n} & -\mathrm{A}-\mathrm{I}_{n} \\
-\mathrm{A}-\mathrm{I}_{n} & \mathrm{xI}_{n}
\end{array}\right) \\
& =\operatorname{det}\left(\mathrm{x}^{2} \mathrm{I}_{n}-\left(\mathrm{A}+\mathrm{I}_{n}\right)^{2}\right)=\operatorname{det}\left(\mathrm{xI}_{n}-\left(\mathrm{A}+\mathrm{I}_{n}\right)\right) \operatorname{det}\left(\mathrm{xI}_{n}+\left(\mathrm{A}+\mathrm{I}_{n}\right)\right) \\
& =\operatorname{det}\left((\mathrm{x}-1) \mathrm{I}_{n}-A\right)(-1)^{n} \operatorname{det}\left(-(x+1) \mathrm{I}_{n}-A\right) \\
& =(-1)^{n} \varnothing_{H}(\mathrm{x}-1) \varnothing_{H}(-\mathrm{x}-1) .
\end{aligned}
$$

2.2) Theorem: Let $H$ be a graph and $v$ a $\lambda$-eigenvector $H$. Let us consider the vector $u+$ with Components $u_{i}^{+}=u_{i^{\prime}}^{+}=v_{i}$, u- with components $u_{i}^{-}=v_{i}$ and $u_{i^{\prime}}^{-}=-v_{i}$ for $1 \leq i, i^{\prime} \leq n$
Then,
$u^{+} \lambda$-eigenvector $\bar{H}$ and $(1+\lambda)$ eigenvector $\hat{H}$
$\bar{u}-\lambda$-eigenvector $\bar{H}$ and $(-1-\lambda)$ eigenvector $\hat{H}$
Given vertex $\mathrm{i}, 1 \leq i \leq n$, all its adjacent vertices are of type j , with $\mathrm{i}(\mathrm{E}): \mathrm{j}$.
Then

$$
\left(\mathrm{A} u^{+}\right)_{i}=\sum_{\substack{E \\ j: i^{\prime}}} u \stackrel{+}{j}=\sum_{\substack{E \\ j: i}} v_{j}=\lambda v_{i}=\lambda u_{i}^{+}
$$

Given vertex $\mathrm{I}^{\prime}, 1 \leq i \leq n$, all its adjacent vertices are of type j , with $\mathrm{i}(\mathrm{E}): \mathrm{j}$.
Then

$$
\left(\mathrm{A} u^{+}\right)_{i^{\prime}}=\sum_{\substack{E \\ j: i^{\prime}}} u \stackrel{+}{j}=\sum_{\substack{E \\ j: i^{\prime}}} v_{j}=\lambda v_{i}=\lambda u_{i}^{+}
$$

By a similar reasoning with $u^{-}$, we obtain

$$
\begin{gathered}
\left(\mathrm{A} u^{-}\right)_{i}=\sum_{\substack{E \\
j: i^{\prime}}} u \stackrel{+}{j^{\prime}}=-\sum_{\substack{E \\
j: i}} v_{j}=-\lambda u_{i-} \text { and } \\
\left(\mathrm{A} u^{-}\right)_{i^{\prime}}=\sum_{\substack{E \\
j: i^{\prime}}} u \bar{j}=\sum_{\substack{E \\
j: i}} v_{j}=-\lambda u_{i}^{\prime} \\
m\left(\lambda_{0}\right)=m\left(\lambda_{5}\right)=m\left(\theta_{0}^{ \pm}\right)=1, \\
m\left(\lambda_{1}\right)=m\left(\lambda_{4}\right)=m\left(\theta_{1}^{ \pm}\right)=4, \\
m\left(\lambda_{2}\right)=m\left(\lambda_{3}\right)=m\left(\theta_{2}^{ \pm}\right)=5,
\end{gathered}
$$

$\therefore u^{-}$Is $-\lambda$-eigenvector of bipartite double graph $\bar{H}$.
Also $1+\lambda,-1-\lambda$ are Eigen values for $u^{+}, u^{-}$Eigen vectors of $\hat{H}$
From the above figures realizing an isomorphism [8, 2] defined by

$$
f: V\left[O_{k}^{0}\right] \rightarrow \mathrm{V}\left[\mathrm{MQ}_{k}\right]
$$

$\begin{array}{cc}u a & u \\ u^{\prime} & \bar{u}\end{array}$
Is clearly directive, according to the definition of bipartite double graph, if u and $v^{\prime}$ are two vertices of $\mathcal{B}_{k}^{o}$.
The middle cube graph $\left[\mathrm{MQ}_{k}\right]$ with $\mathrm{D}=2 \mathrm{k}-1$ by above corollary is isomorphic to $\mathscr{O}_{k}^{o}$.
We prove spectrum of $Q_{2 k-1}$ contains all Eigen values of $\left[\mathrm{MQ}_{k}\right]$,
$\theta_{i}^{+}=(-1)^{i}(\mathrm{k}-\mathrm{i})$ and $=\theta_{i}^{-}=-\theta_{i}^{+}$for $0 \leq i \leq k-1$
With multiplicities $m\left(\theta_{i}^{+}\right)=\mathrm{m}\left(\theta_{i}^{-}\right)=\frac{k-1}{k}\binom{2 k}{i}$

## 3) Conclusion:

In Verification of the above results,

$$
\begin{aligned}
& s p M Q_{3}=\left\{ \pm 2, \pm 1^{2}\right\} \\
& \operatorname{spM} Q_{5}=\left\{ \pm 3, \pm 2^{4}, \pm 1^{5}\right\} \\
& s p M Q_{7}=\left\{ \pm 4, \pm 3^{6}, \pm 2^{14}, \pm 1^{14}\right\} \\
& s p M Q_{9}=\left\{ \pm 5, \pm 4^{8}, \pm 3^{27}, \pm 2^{48}, \pm 1^{42}\right\}
\end{aligned}
$$

For highest degree Distance polynomials of $\left[\mathrm{MQ}_{k}\right]$
$\mathrm{p} 5(3)=\mathrm{p} 5(1)=\mathrm{p} 5(-1)=1$ and $\mathrm{p} 5(2)=\mathrm{p} 5(-1)=\mathrm{p} 5(-3)=-1$. Then,

$$
\begin{aligned}
& m\left(\lambda_{0}\right)=m\left(\lambda_{5}\right)=m\left(\theta_{0}^{ \pm}\right)=1 \\
& m\left(\lambda_{1}\right)=m\left(\lambda_{4}\right)=m\left(\theta_{1}^{ \pm}\right)=4 \\
& m\left(\lambda_{2}\right)=m\left(\lambda_{3}\right)=m\left(\theta_{2}^{ \pm}\right)=5
\end{aligned}
$$
