ABSTRACT

Photovoltaic (PV) systems proposes attractive alternative source of generation because these can be placed near to the load centers when compared with other renewable source of generation. Most of renewable energy systems works in conjunction with the existing electrical grids. Also, inverter technology has an important role to have a safe and reliable grid interconnection operation of renewable energy systems. It is also necessary to generate a high quality power to the grid with reasonable cost. They also must be capable of provide high efficiency conversion with high power factor and low harmonic distortion. For this reason, the control policy must be considered. Therefore, the most important current control techniques are investigated in this paper. This paper proposes the Comparison of Constant Current and Hysteresis Controlling Techniques for on grid PV system.

Keywords: PV System Design, Modeling, DC-DC Boost Converter, PWM Inverter, PLL Constant Current Control, Hysteresis Controlling Techniques.

I. INTRODUCTION

World is moving towards the greener sources of energy to make the planet pollution free and environment friendly. The major utilization of these sources with grid integration is the challenging task. It is therefore Distribution Generation particularly single phase rooftop Photo Voltaic system are major research area for grid integration, since these sources have huge opportunity of generation near loadterminal. The rooftop application involving single phase Distribution Generation's fed with Photo Voltaic source can be not only utilized for household use but the excess energy can be transferred to the grid through proper control scheme and adequate hardware.

Photo Voltaic systems can generate high voltages. Safety is therefore very important in order to avoid accidents and damage of expensive components and equipment. For safety reasons, solar arrays are normally earthed, either by placing a matrix of metal in the ground under the array, or by using conventional earth rods. It is normally not necessary to protect solar array from direct lightning strikes, provided that their mounting structure is well earthed. However, inverters or other electronics controls connected to the array should be protected. Blocking diodes are installed in solar arrays to preventreverse current flows into the modules, which may damage the modules and cause energy losses. By-pass diodes are incorporated into modules to prevent damage of arrays when some cells or modules becomeshaded.

Photo Voltaic system requires regular maintenance to ensure proper operation and the full life of components.

ISSN: 0975- 3583, 0976-2833 VOL 06, ISSUE 01, 2015

Some of the most important maintenance tasks are cleaning of modules front, Removal obstacles, tree branches, etc. Which cause shadowing of the modules, Battery charge check, if it remains very low the system should be re-designed, topping of battery electrolyte.

The rest of components of PV systems require little orno maintenance. The decentralized renewable energy production needs the continuous increase in the electrical energy with the clean environment. Theincreasing energy consumption may overload the distribution grid as well as power station and may cause the negative impact on power availability, security and quality.

The only solution to overcome this problem is integrating the utility grid with the renewable energysystems like solar energy, wind energy or hydro energy. As per the availability of renewable energy sources the grid can be connected to the renewable energy system. Because of abundant availability of solar energy recently the solar power generation systems are getting more attention, more efficient andmore environment friendly as compared to theconventional power generation systems such as fossil fuel, coal or nuclear energy.

II. CIRCUIT CONFIGURATION

The Photo Voltaic systems are still very expensivebecause of higher manufacturing cost of the Photo Voltaic panels, but the energy that drives them the light from the sun is free, available almost everywhere and will be still present for millions of years, even all non-renewable energy sources might be depleted. It has no moving parts this is one of the major advantage of Photo Voltaic technology. Therefore, the Photo Voltaic system is very robust, it has a long lifetime and low maintenance requirements. And, most importantly, it isenvironmentally friendly power generation. The disadvantage of the PV system is that it can supplythe load only in sunny days. Therefore, for improving the performance and supplying the power in all day, it is necessary to hybrid the Photo Voltaic system is that it can supply grid.

The integration of the Photo Voltaic system with the utility grid requires the PWM voltage source converter for interfacing the utility grid and results to some of the interface issues. A prototype current controlled power conditioning system has been developed and tested. This prototype sources 20 kW of power from a photovoltaic array with a maximum power point tracking control.

The disadvantage of this system is the need of high bandwidth current measurement transducers (dc to several times the switching frequency), and the need for relatively high precision in the reference signal generation. Hence, this increases the cost of the system. The inverters suitable for the PV system are central inverters, string inverters, module integrated or module oriented inverters, multi string PV inverterwith new trends has been described below. If these solar inverters are connected with the grid, the control of these inverters can be provided using the phase locked loop. The need and benefits of the distribution technology has been presented in this paper. Single-phase Grid connected Photo Voltaic inverters with the control has been described with its advantages and disadvantages. The three-phasePhotovoltaic power conditioning system with line connection has been proposed with the disturbance of the line voltage which is detected using a fast sensing technique.

The control of the system is provided through the microcontroller. Power electronic systems can also beused for

controlling the solar inverter for interfacing the Solar Power Generation system with the grid the complete design and modeling of the grid connected Photo Voltaic system has been developed to supply the local loads.

This paper proposes the modeling of the grid connected Photo Voltaic system with the Constant Current Controller, which controls the solar inverter for interfacing the grid. The voltage level of DC voltage generated by the Photo Voltaic array is increased using the boost converter and then applied to the 3- ϕ , 2 level Solar inverter. The control of the solar inverter is provided through the ConstantCurrent Controller. This controller uses the Phase Locked Loop and PI controllers. The Phase Locked Loop is used for tracking the phase angle of the grid voltage. The PI controller gains are chosen such that the Constant Current Controller generates the pulses for solar inverter according to the grid voltage. The proposed model is able to supply the 2 MW resistive loads and 30 MW, 2 MVAr load the applicable criteriathat follows.

III. MAXIMUM POWER POINT TRACKING

3.1 P&O Method:

In this approach voltage is periodically given a perturbation & the corresponding output power is compared with that at previous perturbing cycle if the power increases due to that perturbation then the perturbation is continued in the same direction after peak power is reached at the next instant perturbationis reverses power will oscillates at peak power point in order to maintain power variation very small the perturbation size should be very small

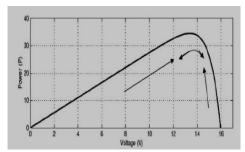

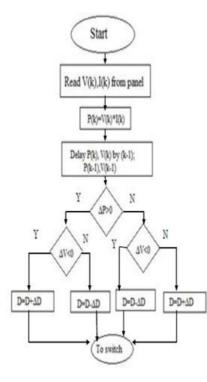

Figure 4. Power vs voltage representation

P&O method is the most frequently used algorithm to track the maximum power due to its simple structure and fewer required parameters. This method finds the maximum power point of PV modules by means of iteratively perturbing, observing and comparing the power generated by the PV modules. It is widely applied to the maximum power point tracker of the photovoltaic system for its features of simplicity and convenience. According to the structure of MPPT it is the relationship between the terminal voltage and output power generated by a PV module. It can be observed that regardless of the magnitude of sun irradiance and terminal voltage of PV modules, the maximum power point is obtained while the condition dP/dV= 0 is accomplished. The slope(dP/dV)of the power can be calculated by the consecutive output voltages and output currents, and can be expressed as follows,

$$\frac{dP}{dV}(n) = \frac{P(n) - P(n-1)}{V(n) - V(n-1)}$$

where P(n) = V(n) I(n)

V. CONCLUSION

This paper proposes the comparison of constant current and hysteresis controlling techniques for PV system integrated with Grid . Here while comparing two controllers ie constant current controller and hysteresis controller, to integrate the PV system with grid. All results will be same for both hysteresis controller and constant current controller, the only difference is in without filter results. When compared with constant current controller, by using hysteresis controller high efficiency conversion with high power factor and low harmonic distortion can be obtained. Hence From the above both constant current and hysteresis controlling techniques can be used to interface the PV system with grid but by using advanced hysteresis controller harmonic content can be reduced.
