ABSTRACT

Introduction: Ki-67 is a nuclear protein and a marker of cell proliferation. Expression of Ki-67 is detected by immunohistochemistry. Breast fibroadenomas, are benign tumours with a maximum incidence in the second decade of life . Some studies indicate that that fibroadenoma is a risk factor for development of breast carcinoma. The present study aimed primarily at assessing the expression of Ki-67 in normal breast and fibroadenoma.

Materials and Methods: The study included a total of 30 cases encompassing, 10 cases of normal breast and 20 cases of fibroadenoma. It was conducted over a period of one year (2022-2023). Grading of Ki-67 was performed based on percentage positivity of cells as low proliferative ($\leq$ 20%) and high proliferative (>20%).

Results: Ki-67 displayed a brown nuclear staining in positive cases which was 100%. There was a significant increase in Ki-67 expression on comparative analysis of normal breast and fibroadenomas (p=0.032).

ISSN: 0975-3583,0976-2833 VOL15, ISSUE 9, 2024

Conclusion: Our study showed an increased level of Ki 67 expression in fibroadenoma breast supporting its proliferative nature. Further studies are needed to understand the behavior of this lesion better.

KeyWords: Fibroadenoma, Ki-67, Immunohistochemistry, Benign Breast Lesion

INTRODUCTION

Ki-67 was identified in 1983 by Gerde et al, and was found in the cell line of Hodgkin lymphoma. [1,2]. It is a nuclear protein and a marker of cell proliferation. Expression of Ki-67 is detected by immunohistochemistry [3]. Ki-67 expression reaches a peak during mitosis and it plays a role in ribosomal RNA synthesis. [1] The encoding gene; MKI6 is located on chromosome 10q25. Previous studies have found that Ki-67 shows low expression level in normal breast tissue. [4].

Breast fibroadenomas are benign tumours composed of an admixture of stromal and epithelial elements. Unlike carcinomatous breast lumps ,fibroadenomas are easily mobile , with well defined edges. [5] The incidence of fibroadenoma peaks during the second decade of life.[6]

Besides its classical form, fibroadenomas may be juvenile, giant or complex [7,2], with some studies indicating that that fibroadenoma is a risk factor for development of breast carcinoma. [8]. The present study primarily aimed at assessing the expression of Ki-67 in normal breast, and fibroadenoma, and comparing the expression in both groups.

MATERIALS AND METHODS

The present study included a total of 30 cases encompassing, 10 cases of normal breast and 20 cases of fibroadenoma. The study was a retrospective study over a period of one year

ISSN: 0975-3583,0976-2833 VOL15, ISSUE 9, 2024

(2022-2023) and was approved by the institutional ethics committee. Clinical details, age , sex of the patients were recorded. Specimens received in our histopathology section were grossed following appropriate protocols and processed. Final diagnosis was given after analyzing hematoxylin and eosin (H & E) stained slides. Immunostaining was performed using Ki-67 (Clone Mib-1, DAKO) in these 30 cases Grading was performed based on percentage positivity of Ki-67 as follows [9]:

Low proliferative: ≤ 20% Ki-67-positive cells

High proliferative: > 20% Ki-67-positive cells

Data regarding clinicopathological parameters were tabulated in Microsoft Excel and statistical analysis (SPSS 23) was performed using Chi Square test. Comparison of Ki-67 staining between normal and fibroadenoma breast cases was performed. P value of <0.05 was taken as statistically significant.

RESULTS

30 cases were analyzed in this study, which included 10 cases of normal breast and 20 cases of fibroadenoma (Fig.1).

Histopathological examination followed by immunohistochemical staining with Ki-67 was performed. The mean age was found to be 28. 9 years. Fibroadenoma was noted in the age group of 20- 32 years, with a mean lesion size of 2.5cm. Following immunohistochemistry, Ki-67 displayed a brown nuclear staining in positive cases. Positive Ki-67 expression in epithelial cells only were considered in all 30 cases. In the present study all cases (100%) showed Ki-67 positivity.

A two tier grading system was followed based on the percentage positivity of cells. In cases of normal breast a majority of cases (90%, n=09) showed low proliferative Ki 67 staining . (Fig 2) In fibroadenoma breast low proliferative Ki 67 staining was seen in 50% cases (n=10) (Fig 3) and 50% cases showed high proliferative staining (n=10). (Fig 4, Fig 5).

There was a statistical significance in the Ki-67 expression on comparative analysis (Fig 6) of normal breast , and fibroadenoma (p=0.032). Out of the 8 cases of fibroadenoma breast having >2.5cm greatest dimension, high proliferative Ki 67 expression was seen in 04 cases. We did not find statistical significance with regard to age and Ki 67 staining percentage (p=0.26) as well as with regards to lesion size and Ki 67 expression. (p=0.12).

DISCUSSION

Immunohistochemistry (IHC) is utilized to understand the expression of various intracellular /cell surface proteins in tissues. [10]. KI-67 is a non-histone nuclear protein expressed throughout the S, G1 and M phases of the cell cycle . A critical characteristic of malignant tissues is their uncontrolled capacity to multiply and progress [11,12]. Being a marker of cell proliferation Ki-67 is seen to be significantly up regulated in cancer of various organ systems. [12]

ISSN: 0975-3583,0976-2833 VOL15, ISSUE 9, 2024

Some authors have described fibroadenoma breast as a hyperplasic lesion due to its clonality. The evolution of neoplasia is reinforced by its monoclonal origin.

Kuijper et al proposed that fibroadenoma can have a bidirectional evolution, that is, either in an epithelial direction leading to carcinoma in situ and subsequently breast carcinoma or in a stromal direction forming a phyllodes tumour. [13]

In our knowledge, presently, there is a great paucity of studies regarding comparative analysis of Ki-67 expression in normal and fibroadenoma breast..

Shoker BS et al (2001) found an increase of Ki-67 expression from normal breast tissue (3.2% percentage positivity) to fibroadenoma breast (9.5% percentage positivity) [14]

Ekundina OV et al, (2022) found a positivity rate of nuclear Ki-67 expression of 20% in normal cases ,which increased progressively to 36% in cases of fibroadenoma . [15]

We found similar results in the present study with an increased expression rate of Ki 67 in cases of fibroadenoma as compared to cases of normal breast.

Prior literature (Lelle et al, 1987) revealed that the growth fractions among various other benign condition of the breast such as cystic breast disease, fibroadenoma and blunt duct adenosis did not vary significantly (average of 3.1% $\pm$ 2.2%). [16]

On clinical diagnosis of fibroadenoma , further evaluation by sonography and fine needle aspiration cytology are advocated, as 30% breast neoplasms initially diagnosed as fibroadenoma, are found to be other lesions post surgery. In women less than age of 35 a more conservative approach to fibroadenoma is indicated with a follow up protocol every 6 months to detect any lesional change. In women older than 35 years mammography is also recommended in view of increased risk of developing carcinoma breast. [17]

Surgical excision is however recommended for fibroadenomas that do not completely regress or remain as is even by the age of 35 years. [17,18] Woman with presence of multiple

ISSN: 0975-3583,0976-2833 VOL15, ISSUE 9, 2024

fibroadenomas are treated in the same manner as those with a single lesion. [17, 18] Katie T et.al. in 2010 assessed the methylation status in a panel of 11 genes in order to learn more about fibroadenoma biology. [19]

CONCLUSION

Our study showed an increased level of Ki 67 expression in fibroadenoma breast supporting its proliferative nature. Further studies with a larger sample size are warranted to understand the behavior and biology of this lesion.
